STEP 6

Metrics & Success Measurement Specification

Prepared by Kirankumar S.

Product Management Launchpad Capstone

North Star: the share of eligible commitments explicitly resolved within 14 days.

1. Executive Summary

This specification defines how to measure whether the proposed Fireflies commitment-closure experience improves honest resolution, while monitoring adoption, workflow friction, and trust. The North Star is the 14-day commitment resolution rate. It must be interpreted alongside the resolution-type mix and guardrails so that apparent improvement does not reward premature completion, coerced acceptance, or silent abandonment.

Measurement decision	Definition
North Star	Percentage of eligible commitments explicitly resolved within 14 calendar days of the defined start timestamp.
Case-study baseline	28% resolved within 14 days.
Case-study target	45% resolved within 14 days within six months.
Required change	+17 percentage points; approximately +60.7% relative to the 28% baseline.
Resolution states	Done, Deliberately dropped, and accepted reassignment, consistent with the case-study definition.
Not resolved	No response/silence, Blocked, Waiting, ownership unconfirmed, and Reassignment pending.

The baseline and target are supplied case-study values. They are not independently validated here. All other proposed metrics and thresholds in this document are measurement recommendations that must be confirmed before implementation.

2. North Star Metric Specification

Metric name

14-Day Commitment Resolution Rate (14D CRR)

Formula

14D CRR = (Number of eligible commitments reaching a qualifying resolution within 14 calendar days of cohort start) ÷ (Total number of eligible commitments in the cohort) × 100

Qualifying resolution

Status/event	Counts as resolved?	Reason
Done	Yes	Explicitly recorded completion.
Deliberately dropped	Yes	Explicitly recorded decision that the commitment is no longer required.
Reassigned after new owner accepts	Yes	The handoff is complete under the supplied case-study definition.
Reassignment pending	No	The new owner has not accepted.
Needs owner confirmation	No	Responsibility is not yet accepted.
In progress	No	Work is not yet resolved.
Blocked / Waiting	No	Work remains unresolved.
No status change / silence	No	Inaction is not a valid resolution.

Cohort start timestamp

Recommended default: use the timestamp when a commitment first becomes a trackable record in Fireflies, whether extracted from a meeting or created manually. This makes the measurement implementable, but it is a product analytics decision—not explicitly fixed by the case-study brief. Confirm this definition before launch and apply it consistently to baseline, treatment, and comparison cohorts.

Eligibility rules to define before launch

- Include only records that meet the agreed definition of a commitment; do not count generic notes or discussion topics as commitments.

- Define whether manually created tasks are eligible for the North Star or reported separately. Recommendation: report extracted commitments and manual tasks separately at first, then combine only if the definitions and use cases are comparable.
- Define duplicate handling when the same commitment appears in multiple meetings or is manually recreated.
- Define whether commitments created before launch are excluded from the primary new-cohort analysis.
- Use a consistent calendar-day versus rolling-24-hour convention; recommendation: 14 × 24 hours from cohort start for event-based calculation, with timezone normalization.
- Keep the denominator fixed for a mature cohort; do not remove unresolved items because they are overdue or inconvenient.
- Define treatment of reopened commitments and status corrections before production reporting.

Why denominator discipline matters

A rate can rise because the product improves outcomes, but it can also rise if harder commitments are excluded, duplicates are removed inconsistently, or the eligible cohort changes. Report the numerator, denominator, exclusions, and resolution-type mix with every headline result.

3. Supporting Metrics

Metric	Definition	Why it matters	Potential failure mode
Owner acceptance rate	Owner-confirmation requests accepted ÷ requests with a recorded response, plus pending share reported separately.	Tests whether suggested ownership is accepted.	A high rate may hide pressure or inaccurate assignments.
Time to owner decision	Median and distribution of time from request to accept/decline/clarification.	Finds handoff friction and delays.	Median alone can hide a long tail; report percentiles.
Unconfirmed-owner share	Eligible commitments still awaiting owner acceptance at defined checkpoints.	Makes ownership ambiguity visible.	Could encourage forced acceptance if used as a target.
Resolution-type mix	Share of qualifying resolutions that are Done, Dropped, or accepted Reassignment.	Shows what is driving North Star movement.	A rising rate driven only by drops or transfers may not mean more work completed.
Blocked / Waiting share	Share of eligible commitments in Blocked or Waiting at a checkpoint.	Shows dependency friction and honest non-terminal status.	Lower is not always better; users may stop reporting blockers.
Time to first meaningful action	Time from cohort start to first accepted owner/status action.	Measures workflow responsiveness.	Can reward trivial updates unless the action definition is controlled.
Repeat-use rate	Activated users who complete another qualifying lifecycle action in a later defined period.	Tests habit formation.	Varies with meeting volume and role; normalize or segment.
Manual task creation rate	Number/share of eligible tasks created manually, segmented from extracted commitments.	Evaluates the supporting capture pathway.	More creation is not automatically better; could indicate extraction gaps or duplicate work.
Correction / reversal rate	Share of commitments whose owner/status is corrected or reversed within a defined window.	Can reveal misassignment or false closure.	A low rate may mean users do not correct errors; pair with qualitative research.

Metric hierarchy

Level	Metric family	Use
North Star outcome	14-day commitment resolution rate	Primary measure of the case-study objective.
Drivers	Owner confirmation, status updates, time to action, blocker reporting	Explain where the lifecycle succeeds or stalls.
Adoption	Exposure, activation, repeat use	Explain whether the experience is being used.
Trust and quality guardrails	Resolution mix, corrections/reopens, decline/clarification, notification burden	Detect superficial or harmful optimization.
Business outcomes	Retention, expansion, renewal, support burden where measurable	Evaluate downstream value; not a substitute for the North Star.

4. Guardrails

Guardrail	What to monitor	Warning interpretation
Honest closure	Resolution-type mix; status corrections/reopens if supported; sampled record review.	Resolution rises while corrections or suspicious terminal-state patterns also rise.
User autonomy	Declines, clarification requests, ownership reversals, qualitative reports of pressure.	Users appear to accept assignments they do not understand or did not agree to.
Notification burden	Reminder dismissal, opt-out, complaint, or notification disablement rates if reminders are implemented.	Prompt volume increases while trust or engagement deteriorates.
Workflow friction	Form abandonment, time-to-update, repeated edits, failed transitions.	The workflow adds work without improving clarity or resolution.
Equity across roles	Segmented adoption and outcomes by role and commitment source, with adequate sample size.	One role bears extra admin work while another receives most of the benefit.
Metric integrity	Event completeness, duplicate rate, missing timestamps, invalid state transitions.	Changes in tracking quality or eligibility rules drive apparent results.

Guardrails should trigger investigation, not automatic blame. For example, a higher Deliberately dropped share may represent more honest prioritization rather than failure; it needs interpretation alongside user context and the overall outcome.

5. Event Tracking Plan

Event	When fired	Required properties	Analytics purpose
commitment_created	A new eligible commitment record is created.	commitment_id, created_at, source_type, creator_role, related_meeting_present, cohort_version	Defines cohort entry and source.
commitment_exposed	A user is shown an eligible commitment surface.	commitment_id, user_id or privacy-safe identifier, timestamp, surface, role	Measures eligible exposure and funnel denominators.
commitment_opened	User opens commitment details.	commitment_id, user_id, timestamp, surface	Measures engagement with the item.
owner_confirmation_requested	A proposed owner is asked to respond.	commitment_id, proposed_owner_id, timestamp	Measures confirmation workflow entry.
owner_confirmation_responded	Proposed owner accepts, declines, or requests clarification.	commitment_id, response, actor_role, timestamp	Measures decision rate and latency.
commitment_status_changed	An explicit status transition occurs.	commitment_id, previous_status, new_status, actor_role, timestamp, reason_present	Builds lifecycle and resolution history.
reassignment_requested	A transfer is proposed.	commitment_id, current_owner_id, proposed_owner_id, timestamp	Measures handoff initiation.
reassignment_accepted	New owner accepts the proposed transfer.	commitment_id, new_owner_id, timestamp	Defines accepted handoff resolution.
commitment_dropped	User deliberately drops the commitment.	commitment_id, actor_role, reason_present, timestamp	Separates dropped from done.
blocker_recorded	User records Blocked or Waiting.	commitment_id, status, blocker_category_if_collected, timestamp	Measures non-terminal friction.
manual_task_created	A user creates a task manually.	task_id, related_meeting_present, timestamp, fields_used	Measures supporting capture behavior.
commitment_corrected_or_reopened	Owner or status is corrected/reopened, if supported.	commitment_id, prior_value, new_value, timestamp, correction_type	Supports integrity checks.

Instrumentation rules

- Use a stable commitment identifier across edits and status changes.
- Record event timestamps consistently and store enough history to reconstruct the state at day 14.
- Do not fire the resolution event when reassignment is merely requested; fire it when acceptance is recorded.

- Do not fire resolution for Blocked, Waiting, silence, or an unconfirmed owner.
- Make event emission idempotent where duplicate delivery is possible.
- Use privacy-minimizing identifiers and collect no meeting content unless necessary for the approved use case.
- Validate events against actual UI behavior before reading experiment results.

6. Cohorts and Experiment Design

Recommended cohorts

Cohort	Definition	Purpose
Baseline cohort	Eligible commitments measured under the current experience using the same eligibility and 14-day rules where historical data supports it.	Establish pre-change performance; document missing historical event coverage.
Pilot treatment	Eligible commitments exposed to the new workflow during the pilot.	Measure adoption, state transitions, and outcome.
Comparison / holdout	Similar eligible commitments or users not exposed to the new workflow during the same period, if feasible and ethical.	Help distinguish feature impact from seasonality and broader changes.
New versus existing users	Segment by account/user tenure at first eligible exposure.	Identify onboarding effects.
Source type	Meeting-extracted commitments versus manually created tasks.	Avoid mixing potentially different behaviors in the headline metric without validation.
Role / team	Segment by user role and team where sample sizes permit.	Detect uneven friction and benefit.

Preferred impact design

If feasible, use a randomized user- or team-level holdout to reduce contamination between participants who share commitments. If randomization is not feasible, use a contemporaneous comparison group or a pre-specified pre/post design and state its limitations. A simple before/after increase alone cannot prove causation.

Measurement window

Each commitment receives a fixed 14-day outcome window from the agreed cohort start timestamp. Only commitments whose full 14-day window has elapsed should enter a finalized cohort result. For early monitoring, report immature cohorts separately and do not treat not-yet-observed outcomes as failures.

Sample size and statistical confidence

Do not invent a sample-size requirement without an expected effect, baseline variance/volume, statistical power, and chosen significance level. Before a controlled experiment, calculate the required sample using the actual eligible commitment volume and the minimum effect worth detecting. If volume is too low, use a longer pilot and treat findings as directional rather than conclusive.

7. Business Impact Measurement

Business question	Potential metric	Evidence required	Caveat
Does the workflow create perceived value?	User-reported usefulness, clarity of ownership, confidence in status.	Short survey/interviews tied to actual use.	Positive sentiment does not prove retention impact.
Does it reduce coordination effort?	Time spent reconstructing status, follow-up count, or duplicate updates if reliably measurable.	Baseline and post-launch measurement with a consistent method.	Self-reported time savings may be biased.
Does it support product retention?	Account retention/renewal for exposed accounts versus a credible comparison.	Longitudinal account data and controls for account mix, tenure, and other product changes.	Correlation does not establish causation.
Does it support expansion?	Expansion or broader adoption among accounts using the workflow.	Account-level usage and commercial data, analyzed with appropriate comparison.	Do not assign revenue impact to the feature without a defensible model.

Does it increase core product engagement?	Repeat commitment actions and continued use of relevant Fireflies surfaces.	Cohort-level event data.	More activity alone is not necessarily more value.

Impact arithmetic

At the stated target, a cohort of 1,000 eligible commitments would have 450 resolved within 14 days versus 280 at the 28% baseline—170 additional resolutions if the target is achieved under the same cohort definition. This illustration is arithmetic only. It does not imply 170 additional completed work items because accepted reassignment and deliberate dropping are also valid resolution states under the case-study definition.

Business attribution rule

Report the North Star first, customer-value evidence second, and downstream business outcomes separately. Do not convert the 17-point target gap into revenue, saved hours, or retention uplift without measured inputs and a transparent model.

8. Reporting Cadence and Decision Rules

Cadence	Review	Decision purpose
Weekly during pilot	Event quality, exposure, activation, owner-response latency, abandonment, trust feedback.	Catch implementation issues and harmful friction early.
At each mature 14-day cohort	North Star rate, denominator, resolution-type mix, guardrails, segment differences.	Assess outcome direction once the cohort window is complete.
At pilot checkpoint	Treatment vs comparison, uncertainty, qualitative evidence, data-quality status.	Decide whether to iterate, extend, expand, or stop.
At six-month target review	Cumulative outcome against 45% target, cohort mix, guardrails, and downstream evidence.	Assess target progress without overstating causal business impact.

Proposed decision logic

- Expand only when event quality is trustworthy, users understand the states, and outcome movement is credible.
- Iterate when users adopt the feature but ownership or resolution transitions remain confusing.
- Investigate before expanding if the North Star improves but Deliberately dropped, Reassigned, or correction rates shift sharply.
- Pause or roll back if users are pressured into acceptance, trust guardrails materially worsen, or event integrity is unreliable.
- If no statistically or practically meaningful improvement is observed, revisit the root-cause hypothesis rather than adding more reminders by default.

9. Data Quality and Interpretation Limits

- Historical baseline data may not have the same event coverage or eligibility rules as the new experience; compare only after reconciliation.
- Commitments vary in complexity, urgency, dependency count, and owner role. Cohort mix can affect resolution rate.
- Users may under-record deliberate drops or blockers, creating a gap between actual behavior and observed status.
- A rise in accepted reassignment can improve the case-study resolution metric without increasing final work completion; report both status mix and any separately defined completion measure.
- A small pilot can reveal usability problems but may not provide enough eligible commitments for reliable outcome estimates.
- Retention and expansion are downstream outcomes with many confounders; use cautious language unless a credible causal design supports stronger claims.

10. Decisions Required Before Launch

Decision	Recommended default	Owner / evidence needed
Commitment cohort start	Timestamp when the commitment first becomes a trackable Fireflies record.	Product + analytics; verify event availability.

Manual task eligibility	Report separately from extracted commitments initially.	Product analytics; assess comparability.
14-day calculation	Fixed 14 × 24-hour window from cohort start, normalized timestamps.	Analytics; implement and test calculation.
Accepted reassignment	Counts as resolved only when the new owner accepts.	Product + engineering; validate state transition.
Reopened/corrected outcomes	Define whether a later reversal changes the day-14 state or is a separate guardrail.	Product analytics; specify event history logic.
Experiment design	Randomized holdout if feasible; otherwise contemporaneous comparison or carefully specified pre/post.	Data science/analytics; sample and contamination assessment.
Rollout threshold	Set before analysis based on minimum meaningful effect, uncertainty, and guardrails.	Product leadership; do not choose after seeing results.

11. Conclusion

The North Star is not a generic task-completion rate; it is the share of eligible commitments explicitly resolved within 14 days under the case-study definition. Supporting metrics explain adoption and workflow friction, while guardrails protect honest closure, user autonomy, and trust.

The next step is to confirm cohort eligibility, instrument state transitions, validate event quality, and define the experiment before launch. The 45% target is the success benchmark to evaluate—not a guaranteed result of the proposed experience.
